Inequality Reducing Properties of Progressive Income Tax Schedules: The Case of Endogenous Income*

Oriol Carbonell-Nicolau† Humberto Llavador‡

October 2015

Abstract

The case for progressive income taxation is often based on the classic result of Jakobsson (1976) and Fellman (1976), according to which progressive and only progressive income taxes—in the sense of increasing average tax rates on income—ensure a reduction in income inequality. This result has been criticized on the ground that it ignores the possible disincentive effect of taxation on work effort, and the resolution of this critique has been a long-standing problem in public finance. This paper provides a normative rationale for progressivity that takes into account the effect of an income tax on labor supply. It shows that a tax schedule is inequality reducing only if it is progressive—in the sense of increasing marginal tax rates on income, and identifies a necessary and sufficient condition on primitives under which progressive and only progressive taxes are inequality reducing.

Keywords: progressive taxation; income inequality; incentive effects of taxation.
JEL classifications: D63, D71.

1 Introduction

A prominent and largely studied normative rationale for progressive income taxation derives from the fundamental result of Jakobsson (1976) and Fellman (1976), which asserts that progressive and only progressive income taxes—in the sense of increasing average tax rates on income—reduce income inequality (regardless of the income distribution they are applied to) according to the relative Lorenz dominance criterion. Jakobsson (1976) and Fellman

A second normative rationale for income tax progressivity is based on the principle of equal sacrifice, which dates back to Samuelson (1947). See Young (1990); Berliant and Gouveia (1993); Ok (1995); Mitra and Ok
(1976) were early contributors to a vast literature on the redistributive effects of tax systems initiated by Musgrave and Thin (1948). This literature is for the most part framed in terms of exogenous income. In particular, while the work of Jakobsson (1976) and Fellman (1976) has been extended in various directions, treatments that incorporate the disincentive effects of taxation tend to emphasize negative results, such as the existence of non-pathological consumer preferences for which progressive tax schedules increase income inequality. As shown in Ebert and Moyes (2007), the Jakobsson-Fellman result can be extended to the case of endogenous income, but in this case inequality reducing tax schedules are no longer completely characterized by average rate progressivity. Instead, the effect of a tax on gross incomes, in addition to its shape, determines the redistributive effect. In particular, a progressive tax schedule may well increase income inequality if the associated elasticity of gross income with respect to non-taxed income is large enough. Allingham (1979) and Ebert and Moyes (2003, 2007) provide examples of such progressive tax schedules.

In this paper we recover a version of the Jakobsson-Fellman result that takes into account the incentive effects of taxation. Our first result states that a piecewise linear tax schedule is inequality reducing (i.e., it reduces income inequality whatever the distribution of abilities) only if it is marginal-rate progressive (i.e., it exhibits nondecreasing marginal tax rates on income). A second result says that the set of all inequality reducing tax schedules is precisely the set of all marginal-rate progressive tax schedules if and only if the elasticity of labor supply with respect to productivity is nondecreasing.

The main results are formulated within the standard Mirrlees model (see Mirrlees, 1971), which provides a suitable framework for the analysis of nonlinear income taxation with endogenous labor supply, and rest on mild assumptions. First, the set of admissible tax schedules is defined as the set of all continuous, piecewise linear maps from pre-tax incomes to tax liabilities that are nondecreasing and preserve the pre-tax ranking of income (i.e., marginal tax rates are less than unity). Second, consumers require an increasingly large and unbounded compensation for an extra unit of labor as their leisure time tends to zero. Finally, consumer preferences satisfy agent monotonicity, a condition introduced by Mirrlees (1971, Assumption B, p. 182) and named by Seade (1982). This condition requires that the marginal rate of substitution of gross income for consumption be nonincreasing with...

7 In other words, the marginal rate of substitution of labor for consumption tends to infinity as leisure time vanishes.
productivity, and, as pointed out by Mirrlees (1971), is equivalent to the condition that, in the absence of taxation, consumption increases as the wage rate increases.

The paper is organized as follows. Section 2 lays out the formal setting. The main results, together with sketches of their proofs, are presented in Section 3. Technical proofs are relegated to the Appendix.

2 The model

Consider an economy with a finite number \( n \geq 2 \) of individuals. The welfare of an individual is measured by a continuous utility function \( u : \mathbb{R}_+ \times [0,1] \to \mathbb{R} \) defined over consumption-labor pairs \((c,l) \in \mathbb{R}_+ \times [0,1]\) such that \( u(c,l) \) is strictly increasing in \( c \) for each \( l \in [0,1] \), and \( u(c,\cdot) \) is strictly decreasing in \( l \) for each \( c \in \mathbb{R}_+ \). It is assumed that \( u \) is strictly quasiconcave on \( \mathbb{R}_+ \times [0,1] \) and has continuous partial derivatives on \( \mathbb{R}_+ \times [0,1] \),

\[
u_c(c,l) := \frac{\partial u(c,l)}{\partial c} \quad \text{and} \quad u_l(c,l) := \frac{\partial u(c,l)}{\partial l}.
\]

For \((c,l) \in \mathbb{R}_+ \times [0,1]\), let

\[
MRS(c,l) := \frac{u_l(c,l)}{u_c(c,l)}
\]

denote the marginal rate of substitution of labor for consumption. (Observe that \( MRS(c,l) \geq 0 \) for each \((c,l)\).) We assume that, for each \( c > 0 \),

\[
\lim_{l \to 1} MRS(c,l) = +\infty \quad \text{and} \quad 0 < \lim_{l \to 0} MRS(c,l) < +\infty.
\]

The second condition is readily acceptable. According to the first condition, the compensation required by an individual for an extra unit of working time tends to infinity as the agent’s leisure time approaches zero.

Let \( \mathcal{U} \) denote the set of all utility functions satisfying the above conditions.

Prior to formulating the agents’ utility maximization problem, we need the formal definition of a tax schedule. Throughout the sequel we confine attention to piecewise linear tax schedules.

**Definition 1.** Let \((a_0, t, \bar{y}) = (a_0, (t_0,\ldots,t_K), (\bar{y}_0,\ldots,\bar{y}_K))\), where \( a_0 \geq 0 \), \( K \in \mathbb{Z}_+ \), \( t_k \in [0,1] \) for each \( k \in (0,\ldots,K) \), \( t_k \neq t_{k+1} \) whenever \( k \in (0,\ldots,K-1) \) and \( K \geq 1 \), and \( 0 = \bar{y}_0 < \cdots < \bar{y}_K \). A **piecewise linear tax schedule** is a real-valued map \( T \) on \( \mathbb{R}_+ \) uniquely determined by \((a_0, t, \bar{y})\) as follows:

\[
T(y) := \begin{cases} 
-a_0 + t_0 y & \text{if } 0 = \bar{y}_0 \leq y \leq \bar{y}_1, \\
-a_0 + t_0 \bar{y}_1 + t_1 (y - \bar{y}_1) & \text{if } \bar{y}_1 < y \leq \bar{y}_2, \\
\vdots & \\
-a_0 + t_0 \bar{y}_1 + t_1 (\bar{y}_2 - \bar{y}_1) + \cdots + t_{K-1}(\bar{y}_K - \bar{y}_{K-1}) + t_K (y - \bar{y}_K) & \text{if } \bar{y}_K < y.
\end{cases}
\]
Here \( T(y) \) is interpreted as the tax liability for gross income level \( y \).

Letting \( \bar{y}_{K+1} := +\infty \), the tax schedule corresponding to the vector \((a_0, t, \bar{y})\) can be succinctly expressed as

\[
T(y) = t_k y - \alpha_k \quad \text{for} \quad \bar{y}_k \leq y \leq \bar{y}_{k+1}, \quad k \in \{0, \ldots, K\},
\]

where \( \alpha_k := a_{k-1} + (t_k - t_{k-1})\bar{y}_k \) for \( k \in \{1, \ldots, K\} \).

We write \((a_0, t, \bar{y})\) and the associated map \( T \) interchangeably. The set of piecewise linear tax schedules is denoted by \( \mathcal{T} \).

Individuals differ in their abilities. An ability distribution is a vector \( a = (a_1, \ldots, a_n) \in \mathbb{R}^n_+ \) such that \( a_1 \leq \cdots \leq a_n \) (that is, without loss of generality, individuals are sorted in ascending order according to their ability). The set of all ability distributions is denoted by \( \mathcal{A} \).

An agent of ability \( a > 0 \) who chooses \( l \in [0, 1] \) units of labor and faces a tax schedule \( T \in \mathcal{T} \) consumes \( c = al - T(al) \) units of the good and obtains a utility of \( u(c, l) \). Thus, the agent’s problem is

\[
\max_{l \in [0, 1]} u(al - T(al), l). \tag{1}
\]

Because the members of \( \mathcal{U} \) and \( \mathcal{T} \) are continuous, for given \( u \in \mathcal{U}, a > 0 \), and \( T \in \mathcal{T} \), the optimization problem in (1) has a solution, although it need not be unique. A solution function is a map \( l^u : \mathbb{R}_+ \times \mathcal{T} \rightarrow [0, 1] \) such that \( l^u(a, T) \) is a solution to (1) for each \((a, T) \in \mathbb{R}_+ \times \mathcal{T}\). The pre-tax and post-tax income functions associated to a solution function \( l^u \), denoted by \( y^u : \mathbb{R}_+ \times \mathcal{T} \rightarrow \mathbb{R}_+ \) and \( x^u : \mathbb{R}_+ \times \mathcal{T} \rightarrow \mathbb{R}_+ \) respectively, are given by

\[
y^u(a, T) := al^u(a, T) \quad \text{and} \quad x^u(a, T) := al^u(a, T) - T(al^u(a, T)).
\]

The superscript \( u \) will sometimes be omitted to lighten notation.

Given \( a > 0 \), let \( U^a : \mathbb{R}_+ \times [0, a] \rightarrow \mathbb{R} \) be defined by \( U^a(c, y) := u \left( c, \frac{y}{a} \right) \). For \((c, y, a) \in \mathbb{R}_+^2 \times \mathbb{R}_+^+ \) with \( y < a \), define

\[
U^a_c(c, y) := \frac{\partial U^a(c, y)}{\partial c}, \quad U^a_y(c, y) := \frac{\partial U^a(c, y)}{\partial y}, \quad \text{and} \quad \eta^a(c, y) := -\frac{U^a_y(c, y)}{U^a_c(c, y)}.
\]

Observe that \( \eta^a(c, y) \) can be viewed as the marginal rate of substitution of gross income for consumption at \((c, y)\) for an agent with ability \( a \).

The following condition plays an important role in the proofs of our main results. It was introduced by Mirrlees (1971, Assumption B, p. 182) and termed agent monotonicity by Seade (1982). Agent monotonicity is a single-crossing condition on the agents’ indifference curves in the space of gross income-consumption pairs \((y, c)\).

**Definition 2.** A utility function \( u \in \mathcal{U} \) satisfies agent monotonicity if \( \eta^a(c, y) \geq \eta^{a'}(c, y) \) for each \((c, y) \in \mathbb{R}_+^2 \) and \( 0 < a < a' \) with \( y < a \).
The set of all the members of \( \mathcal{U} \) satisfying agent monotonicity is represented as \( \mathcal{U}^* \).

An income distribution is a vector \( z = (z_1, \ldots, z_n) \in \mathbb{R}^n_+ \) of incomes arranged in increasing order, i.e., \( z_1 \leq \cdots \leq z_n \); here \( z_1 \) denotes the income of the poorest agent, \( z_2 \) denotes the income of the second poorest agent, and so on.

In this paper we use the standard relative Lorenz ordering to make inequality comparisons between income distributions. Given two income distributions \( z = (z_1, \ldots, z_n) \) and \( z' = (z'_1, \ldots, z'_n) \) with \( z_n, z'_n > 0 \), we say that \( z \) is at least as equal as \( z' \) if \( z \) Lorenz dominates \( z' \), i.e., if
\[
\frac{\sum_{i=1}^{k} z_i}{\sum_{i=1}^{n} z_i} \geq \frac{\sum_{i=1}^{k} z'_i}{\sum_{i=1}^{n} z'_i}, \quad \text{for all } k \in \{1, \ldots, n\}.
\]

For \( u \in \mathcal{U}^* \), and given pre-tax and post-tax income functions \( y_u \) and \( x_u \), an ability distribution \( a = (a_1, \ldots, a_n) \in \mathcal{A} \) and a tax schedule \( T \in \mathcal{F} \) determine a pre-tax income distribution
\[
(y_u(a_1, T), \ldots, y_u(a_n, T))
\]
and a post-tax income distribution
\[
(x_u(a_1, T), \ldots, x_u(a_n, T)).
\]

In the absence of taxation, i.e., if \( T \equiv 0 \), one has
\[
(y_u(a_1, 0), \ldots, y_u(a_n, 0)) = (x_u(a_1, T), \ldots, x_u(a_n, T)).
\]

Definition 3. Let \( u \in \mathcal{U} \). A tax schedule \( T \in \mathcal{F} \) is income inequality reducing with respect to \( u \) (u-iir) if \( (x^u(a_1, T), \ldots, x^u(a_n, T)) \) Lorenz dominates \( (y^u(a_1, 0), \ldots, y^u(a_n, 0)) \) for each pre-tax and post-tax income functions \( y^u \) and \( x^u \) and each ability distribution \( (a_1, \ldots, a_n) \in \mathcal{A} \).

3 The main results

We begin by defining two important subclasses of the set \( \mathcal{F} \) of piecewise linear tax schedules.

Definition 4. A tax schedule \( T \in \mathcal{F} \) is marginal-rate progressive if it is a convex function.

The set of all marginal-rate progressive tax schedules in \( \mathcal{F} \) is denoted by \( \mathcal{F}_{prog} \).

Definition 5. A tax schedule \( T \in \mathcal{F} \) is proportional if \( T(y) = t_0 y \) for all \( y \in \mathbb{R}_+ \) and some \( t_0 \in [0, 1) \).

We now present the two main results of the paper. Theorem 1 states that only marginal-rate progressive tax schedules can be inequality reducing. Theorem 2 asserts that if there exists at least one proportional, inequality reducing (possibly neutral) tax schedule, then the set of all inequality reducing tax schedules coincides with the set of marginal-rate progressive tax schedules.

---

8Under the agent monotonicity condition, in both cases the vector components are arranged in increasing order. See Lemma 1 below.
Theorem 1. Given \( u \in \mathcal{U}^* \), a tax schedule in \( \mathcal{T} \) is \( u \)-iir only if it is marginal-rate progressive.

Theorem 2. Given \( u \in \mathcal{U}^* \), the set of all \( u \)-iir tax schedules in \( \mathcal{T} \) equals \( \mathcal{T}_{\text{prog}} \) if and only if there exists an \( u \)-iir proportional tax schedule in \( \mathcal{T} \).

Remark. The reader may wish to consider tax schedules that are inequality reducing not only for a fixed utility function \( u \in \mathcal{U}^* \) but rather for all utility functions \( u \) in some subdomain \( \mathcal{U}^{**} \) of \( \mathcal{U}^* \). Given \( \mathcal{U}^{**} \subseteq \mathcal{U}^* \), call a tax schedule \( \mathcal{T} \in \mathcal{T} \) income inequality reducing with respect to \( \mathcal{U}^{**} \) (\( \mathcal{U}^{**}\)-iir) if for each pre-tax and post-tax income functions \( x^u \) and \( y^u \), each \( (a_1, \ldots, a_n) \in \mathcal{A} \), and every \( u \in \mathcal{U}^{**} \), Theorems 1 and 2 immediately give the following variants in terms of this strengthening of Definition 3.

Corollary 1 (to Theorem 1). Given \( \mathcal{U}^{**} \subseteq \mathcal{U}^* \), a tax schedule in \( \mathcal{T} \) is \( \mathcal{U}^{**}\)-iir only if it is marginal-rate progressive.

Corollary 2 (to Theorem 2). Given \( \mathcal{U}^{**} \subseteq \mathcal{U}^* \), the set of all \( \mathcal{U}^{**}\)-iir tax schedules in \( \mathcal{T} \) equals \( \mathcal{T}_{\text{prog}} \) if and only if there exists an \( \mathcal{U}^{**}\)-iir proportional tax schedule.\(^9\)

3.1 Proofs of the main results

In this subsection, we present the main arguments for the proofs of Theorems 1 and 2 and relegate technical details to the Appendix. We begin with three preparatory lemmas. The first lemma says that pre-tax and post-tax income functions are monotone in \( a \), and that the solution to the agents’ maximization problem (1) is almost always unique. This result is well-known (see Mirrlees, 1971, Theorem 1 and the ensuing discussion on p. 183).

Lemma 1. Let \( u \in \mathcal{U}^* \), \( T \in \mathcal{T} \). For every pre-tax and post-tax income functions \( x^u \) and \( y^u \), the maps \( a \rightarrow x^u(a,T) \) and \( a \rightarrow y^u(a,T) \) are nondecreasing on \( \mathbb{R}_{++} \). Moreover, given \( T \in \mathcal{T} \), there is a unique solution to (1) for all \( a > 0 \), except for a set of measure zero.

Lemma 2. Given \( u \in \mathcal{U} \), for each \( (c,y) \in \mathbb{R}_{++}^2 \) and \( q \in (0, +\infty) \), there exists an \( a > y \) such that \( \eta^a(c,y) = q \).

Proof. Observe that

\[
\lim_{a \to \infty} \eta^a(c,y) = \lim_{a \to \infty} \frac{1}{a} \text{MRS}(c,y/a) = 0 \quad \text{and} \quad \lim_{a \downarrow y} \eta^a(c,y) = \lim_{a \downarrow y} \frac{1}{a} \text{MRS}(c,y/a) = +\infty.
\]

Since the map \( a \rightarrow \eta^a \) is continuous, the lemma follows from the Intermediate Value Theorem. \( \blacksquare \)

The third lemma gives an alternative characterization of an inequality reducing tax schedule (recall Definition 3); its proof is relegated to Appendix A.\(^{10}\)

\(^9\)Observe that in the particular case when \( \mathcal{U}^{**} = \mathcal{U}^* \) (or \( \mathcal{U}^{**} = \mathcal{U} \) for that matter), Corollary 2 is vacuous, for we know (as per Proposition 3 in Ebert and Moyes (2007)) that there exist preferences for which no proportional tax is inequality reducing.

\(^{10}\)Lemma 3 is analogous to Lemma 1 in Jakobsson (1976), Proposition 2.1 in Moyes (1994), and Lemma 2 in Ebert and Moyes (2007).
Lemma 3. Given $u \in \mathcal{U}$, a tax schedule $T \in \mathcal{T}$ is u-iir if and only if for any ability distribution $a \in \mathcal{A}$ and for any pre-tax and post-tax income functions $y^u$ and $x^u$, 

$$\frac{x^u(a_i, T)}{y^u(a_i, 0)} \geq \frac{x^u(a_{i+1}, T)}{y^u(a_{i+1}, 0)} \quad \forall i \in \{1, \ldots, n-1\}. \quad (2)$$

3.1.1 Proof of Theorem 1

The following lemma plays an essential role in the proof of Theorem 1.

Lemma 4. Let $u \in \mathcal{U}^*$ and $T \in \mathcal{T}$, and let $x^u$ be a post-tax income function. Then the map $a \mapsto x^u(a, T)$ is continuous on $\mathbb{R}_{++}$ if and only if $T$ is marginal-rate progressive.

The formal proof of Lemma 4 is furnished in Appendix B. Here we provide intuition for this result. Consider the agents’ budget line in the space of pre-tax and post-tax income pairs $(y, x)$ for a given tax schedule. If agents face a marginal-rate progressive tax schedule $T$, this budget line is concave, and since preferences satisfy strict quasiconcavity, there is a unique optimal pre-tax and post-tax income pair for each agent; in this case the continuity of the map $a \mapsto x^u(a, T)$ follows from Berge’s Maximum Theorem. Under a non-convex tax $T$, on the other hand, the budget line must be non-concave somewhere, as the black line in Figure 1. In this case there are multiple optimal pre-tax and post-tax income pairs for some ability level, say $a^*$ (points $(y, x)$ and $(\bar{y}, \bar{x})$ in Figure 1). Given the agent monotonicity condition (recall Definition 2), this multiplicity generates a discontinuity of the map $a \mapsto x^u(a, T)$ at $a^*$. Thus, continuity of the map $a \mapsto x^u(a, T)$ implies convexity of $T$. 

Figure 1: Figure for Theorem 1
Given Lemma 4, Theorem 1 can be concisely proven as follows. Take \( u \in \mathcal{U}^\ast \). By Lemma 3, we only need to find, for each \( T \in \mathcal{T} \) that is not marginal-rate progressive, \( a \in \mathcal{A} \) and pre-tax and post-tax income functions \( y^u \) and \( x^u \) violating (2). Note that given \( y^u \) and \( x^u \), an ability distribution \( a \in \mathcal{A} \) will violate (2) if the map \( a \mapsto x^u(a, T) \) defined on \( \mathbb{R}_+ \) has a discontinuity point and the map \( a \mapsto y^u(a, 0) \) defined on \( \mathbb{R}_+ \) is continuous. Indeed, in this case, letting \( a^* > 0 \) be a discontinuity point for the map \( a \mapsto x^u(a, T) \),

\[
\lim_{a \uparrow a^*} x^u(a, T) < \lim_{a \downarrow a^*} x^u(a, T) \quad \text{and} \quad \lim_{a \uparrow a^*} y^u(a, 0) = \lim_{a \downarrow a^*} y^u(a, 0),
\]

since \( x^u \) is nondecreasing (Lemma 1), implying

\[
\lim_{a \uparrow a^*} \frac{x^u(a, T)}{y^u(a, 0)} < \lim_{a \downarrow a^*} \frac{x^u(a, T)}{y^u(a, 0)}.
\]

Thus, Theorem 1 is a consequence of Lemma 4. (Observe that \( x^u(\cdot, T) = y^u(\cdot, 0) \) whenever \( T \equiv 0 \).)

### 3.1.2 Proof of Theorem 2

To lighten notation, we will omit the superscript \( u \) throughout the proof.

It is clear that if the set of all \( u \)-iir tax schedules in \( \mathcal{T} \) equals \( \mathcal{T}_{\text{prog}} \), then there exists an \( u \)-iir proportional tax schedule.

Suppose that there exists an \( u \)-iir proportional tax schedule in \( \mathcal{T} \). By Theorem 1 it follows that the set of all \( u \)-iir tax schedules in \( \mathcal{T} \) is contained in \( \mathcal{T}_{\text{prog}} \). It remains to show the reverse containment. Let \( T = (a_0, t, \bar{y}) \in \mathcal{T} \) be marginal-rate progressive (recall Definition 1). By Lemma 3, we only need to show that condition (2) holds for any ability distribution \( a \in \mathcal{A} \) and for any pre-tax and post-tax income functions \( y^u \) and \( x^u \).

First, given the existence of a proportional tax schedule that is \( u \)-iir, Propositions 2 and 3 in Ebert and Moyes (2007) imply that all linear tax schedules are \( u \)-iir.\footnote{A nondecreasing elasticity of labor supply with respect to productivity is necessary and sufficient for a proportional tax schedule to be inequality reducing (Ebert and Moyes, 2007, Proposition 3) and sufficient for a linear tax schedule to be inequality reducing (Ebert and Moyes, 2007, Proposition 2).}

Now, for each income threshold \( \bar{y}_k \) of \( T \), define the linear tax schedule \( T_k(y) := t_k y - \alpha_k \) for \( k \in \{0, \ldots, K\} \), where \( \alpha_k := \alpha_{k-1} + (t_k - t_{k-1}) \bar{y}_k \) for \( k \in \{1, \ldots, K\} \).

Pre-tax and post-tax income functions, \( y \) and \( x \), are uniquely defined, since preferences are strictly quasiconcave and the tax function \( T \) is convex. For \( k \in \{1, \ldots, K\} \), define the abilities \( a_k^- \) and \( a_k^+ \) such that

\[
a_k^- := \min \{ a : y(a, T_{k-1}) = \bar{y}_k \} \quad \text{and} \quad a_k^+ := \max \{ a : y(a, T_k) = \bar{y}_k \}
\]

(see Figure 2). Lemma 2 guarantees that \( a_k^- \) and \( a_k^+ \) exist and are well defined for all \( k \in \{1, \ldots, K\} \).
Furthermore, since $T$ is marginal-rate progressive (and hence $t_{k-1} \leq t_k$ for all $k \in \{1, \ldots, K\}$), agent monotonicity (Definition 2) implies that $a^-_k \leq a_k \leq a^-_{k+1}$.

Next, define the following family of sets covering $(0, +\infty)$:

$$\mathcal{A} := \left\{ (0, a^-_1], \{[a^-_k, a_k]\}_{k=1}^{K-1}, [a_k, a^-_{k+1}]\}_{k=1}^{K}, [a_K, +\infty) \right\}.$$

We first show that condition (2) is satisfied for ability distributions contained in each element of the family $\mathcal{A}$.

(i) Consider first the interval $(0, a^-_1]$. Observe that $y(a, T) = y(a, T_0)$ for all $a \leq a^-_1$. Because $T_0$ is a linear tax, it is u-iir, and so Lemma 3 gives

$$\frac{x(a, T)}{y(a, 0)} = \frac{x(a, T_0)}{y(a, 0)} \geq \frac{x(a', T)}{y(a', 0)} = \frac{x(a', T_0)}{y(a', 0)} \quad \forall a \leq a' \leq a^-_1. \quad (3)$$

(ii) For $[a_K, +\infty)$, a symmetric argument shows that

$$\frac{x(a, T)}{y(a, 0)} \geq \frac{x(a', T)}{y(a', 0)} \quad \forall a_K \leq a \leq a'. \quad (4)$$

12 Observe that, letting $\bar{x}_k = x(a^-_k, T) = x(a_k, T), \eta^{\bar{x}_k}_{a_k}(\bar{x}_k, \bar{y}_k) = 1 - t_{k-1} > 1 - t_k = \eta^{a_k}(\bar{x}_k, \bar{y}_k)$. On the other hand, $\eta^{a_k}(\bar{x}_{k+1}, \bar{y}_{k+1}) > 1 - t_k = \eta^{a_{k+1}}(\bar{x}_{k+1}, \bar{y}_{k+1})$. 

Figure 2: Figure for Theorem 2
(iii) Now consider the interval $[a_k^-, a_k]$ for $k \in \{1, \ldots, K\}$. Observe that

$$y(a_k, T) = y(a_k, T_k) = \bar{y}_k = y(a_k^-, T_{k-1}) = y(a_k^-, T).$$

Hence, by monotonicity of the map $a \mapsto y(a, T)$ (Lemma 1), $y(a, T) = \bar{y}_k$ for all $a \in [a_k^-, a_k]$. Therefore, because $y(a', 0) \geq y(a, 0)$ for all $a_k^- \leq a \leq a_k$ by Lemma 1,

$$\frac{x(a, T)}{y(a, 0)} = \frac{\bar{y}_k - T(\bar{y}_k)}{y(a, 0)} \geq \frac{\bar{y}_k - T(\bar{y}_k)}{y(a', 0)} = \frac{x(a', T)}{y(a', 0)} \quad \forall a, a' \in [a_k^-, a_k], a \leq a'.$$  

(iv) Finally, consider the interval $[a_k, a_{k+1}^-]$ for $k \in \{1, \ldots, K - 1\}$. By construction, we have $y(a, T) = y(a, T_k)$ for all $a \in [a_k, a_{k+1}^-]$. Therefore, since $T_k$ is a linear (hence $u$-iir) tax, Lemma 3 gives

$$\frac{x(a, T)}{y(a, 0)} = \frac{x(a, T_k)}{y(a, 0)} \geq \frac{x(a', T_k)}{y(a', 0)} = \frac{x(a', T)}{y(a', 0)} \quad \forall a, a' \in [a_k, a_{k+1}^-], a \leq a'.$$  

Combining equations (3)-(6) we obtain (2) for every $a \in \mathcal{A}$.

4 Concluding remarks

This paper provides a normative foundation for progressive income taxes. Our work—which goes beyond the classic results of Jakobsson (1976) and Fellman (1976) in that it takes into account the disincentive effects of taxation on work effort—relies on three basic conditions: the agent monotonicity condition, which is standard in the literature on nonlinear taxation with endogenous labor supply; piecewise linearity of admissible tax schedules, an ubiquitous feature of actual statutory tax schedules; and an increasingly large marginal rate of substitution of labor for consumption for vanishingly small amounts of leisure time. The latter condition fails in the Jakobsson-Fellman setting, viewed in the Mirrlees framework as the particular case of costless work effort.

Theorem 1 implies that tax schedules aimed at reducing income inequality must be marginal-rate progressive. Theorem 2 can be combined with the results on proportional taxation in Ebert and Moyes (2007) to obtain a necessary and sufficient condition on primitives under which the members of $\mathcal{I}_{\text{prog}}$, and only the members of $\mathcal{I}_{\text{prog}}$, are inequality reducing. In fact, if in the absence of taxation income is differentiable with respect to productivity, then a proportional tax schedule is $u$-iir (for $u \in \mathcal{U}^*$) if and only if the elasticity of labor supply with respect to productivity is nondecreasing (Ebert and Moyes, 2007, Proposition 3).

Thus, given $u \in \mathcal{U}^*$, a nondecreasing elasticity of labor supply with respect to productivity is necessary and sufficient for the set of all $u$-iir tax schedules to be precisely $\mathcal{I}_{\text{prog}}$. The empirical evidence is consistent with this elasticity condition. For instance, Chetty (2012, Table I) reports observed hours and taxable income elasticities for 21 studies and observes
that estimated elasticities for top income earners (averaging 0.84) are significantly larger than elasticities estimated for the whole population (averaging 0.15).\textsuperscript{13,14}

We conclude with a philosophical comment. This paper focuses on the reduction of income inequality through the tax system, as does virtually all the related literature. Some authors have suggested that considering instead the welfare inequality reducing properties of taxes might be more reasonable. After all, individuals ultimately care about their well-being. While we believe that this idea deserves further investigation, we would like to point out that a meaningful characterization of the welfare inequality reducing properties of progressive tax schedules seems problematic even in the standard context of exogenous incomes. Indeed, consider the marginal-rate progressive (hence income inequality reducing) tax function \( T(y) := y - \ln(y + 1) \), together with the utility function \( u(x) := \ln(x) \); since the ratio \( \frac{u(y - T(y))}{u(y)} = \frac{\ln(\ln(y + 1))}{\ln(y)} \) is strictly increasing in \( y \), it follows from Lemma 1 in Jakobsson (1976) that \( T \) is welfare inequality increasing.\textsuperscript{15}

\section*{Appendix}

\textbf{A Proof of Lemma 3}

\textbf{Lemma 3.} Given \( u \in \mathcal{U} \), a tax schedule \( T \in \mathcal{T} \) is \textit{u-iir} if and only if for any ability distribution \( \alpha \in \mathcal{A} \) and for any pre-tax and post-tax income functions \( y^u \) and \( x^u \),

\begin{equation}
    \frac{x^u(a_i, T)}{y^u(a_i, 0)} \geq \frac{x^u(a_{i+1}, T)}{y^u(a_{i+1}, 0)} \quad \forall i \in \{1, \ldots, n - 1\}. \tag{7}
\end{equation}

\textbf{Proof.} We adapt the proof of Lemma 2 in Ebert and Moyes (2007).\textsuperscript{16}

\((\Leftarrow)\) A tax schedule is \textit{u-iir} if condition (7) holds for any \( \alpha \in \mathcal{A} \) and any pre-tax and post-tax income functions \( y^u \) and \( x^u \). This is a direct consequence of Marshall et al. (2011, B.1.b in chapter 5), since for each \( \alpha \in \mathcal{A} \), \( x^u(a_i, T) > 0 \) for each \( i \in \{1, \ldots, n\} \) and \( \sum_{i=1}^n y^u(a_i, 0) > 0 \).

\((\Rightarrow)\) Suppose that there exists \( \alpha \in \mathcal{A} \) and \( x^u \) and \( y^u \) such that

\begin{equation}
    \frac{x^u(\alpha_h, T)}{y^u(\alpha_h, 0)} < \frac{x^u(\alpha_{h+1}, T)}{y^u(\alpha_{h+1}, 0)} \quad \text{for some } h \in \{1, \ldots, n - 1\}. \tag{8}
\end{equation}

Choose \( \alpha^* := (a^*_1, \ldots, a^*_n) \) where \( a^*_i := \alpha_h \) and \( a^*_i := \alpha_{h+1} \) for \( i \in \{2, \ldots, n\} \). By definition, \( a^*_1 < a^*_2 = \cdots = a^*_n \). It follows that \( x^u(a^*_1, T) = x^u(\alpha_h, T) \) and \( x^u(a^*_i, T) = x^u(\alpha_{h+1}, T) \) for \( i \in \{2, \ldots, n\} \).

\textsuperscript{13}See also Goolsbee (2000), Saez (2004), and Heim (2009).

\textsuperscript{14}These findings should be taken with a grain of caution, for the estimation of labor elasticities remains a controversial issue (see the recent surveys by McClelland and Mok (2012) and Keane and Rogerson (2012)).

\textsuperscript{15}According to Ebert and Moyes (2007, footnote 19), in the case of exogenous income, the Jakobsson-Fellman result can be stated in terms of welfare inequality if and only if the utility function is isoelastic, \textit{i.e.}, it takes the form \( u(x) = x^\chi \), where \( \chi \) and \( \xi \) are constants.

\textsuperscript{16}Since we do not assume the existence of a unique solution to the agents’ maximization problem, (1), Lemma 2 in Ebert and Moyes (2007) does not subsume Lemma 3.
And similarly for $y$. From (8),
\[
\frac{x^u(a_1^*, T)}{y^u(a_1^*, 0)} < \frac{x^u(a_2^*, T)}{y^u(a_2^*, 0)} = \cdots = \frac{x^u(a_n^*, T)}{y^u(a_n^*, 0)}.
\]

Appealing to Marshall et al. (2011, B.1.b in Chapter 5),
\[
\left( \frac{x^u(a_1^*, T)}{\sum_j x^u(a_j^*, T)} , \ldots , \frac{x^u(a_n^*, T)}{\sum_j x^u(a_j^*, T)} \right)
\]
is majorized by
\[
\left( \frac{y^u(a_1^*, 0)}{\sum_j y^u(a_j^*, 0)} , \ldots , \frac{y^u(a_n^*, 0)}{\sum_j y^u(a_j^*, 0)} \right).^{17}
\]

Therefore,
\[
\sum_{i=1}^k \frac{x^u(a_i^*, T)}{\sum_j x^u(a_j^*, T)} \leq \sum_{i=1}^k \frac{y^u(a_i^*, 0)}{\sum_j y^u(a_j^*, 0)} \quad \forall k \in \{1, \ldots, n\}.
\]

That is, $(y^u(a_1^*, 0), \ldots, y^u(a_n^*, 0))$ Lorenz dominates $(x^u(a_1^*, T), \ldots, x^u(a_n^*, T))$, and hence $T$ is not $u$-iir.

\section*{B Proof of Lemma 4}

\textbf{Lemma 4.} Let $u \in \mathcal{U}^*$ and $T \in \mathcal{T}$, and let $x^u$ be a post-tax income function. Then the map $a \mapsto x^u(a, T)$ is continuous on $\mathbb{R}_{++}$ if and only if $T$ is marginal-rate progressive.

\textit{Proof.} Take $u \in \mathcal{U}^*$ and $T = (a, t, y) \in \mathcal{T}$. First observe that $T$ is marginal-rate progressive (i.e., convex) if and only if the map $y \mapsto x = y - T(y)$ defined on $\mathbb{R}_+$ is concave.

$(\Leftarrow)$ Let $T$ be marginal-rate progressive. Because the map $y \mapsto x(y) := y - T(y)$ is concave and $u(c, l)$ is strictly quasiconcave (and strictly increasing (resp. decreasing) in $c$ (resp. $l$)), for each $a > 0$ the problem
\[
\max_{y \in [0,a]} u \left( y - T(y), \frac{y}{a} \right)
\]
has a unique solution. Consequently, there is a unique map that assigns to each ability level $a > 0$ the pre-tax income $y(a)$ that solves (9), and by virtue of Berge’s Maximum Theorem, this map is continuous. But then the map $a \mapsto y(a) - T(y(a))$ defined on $\mathbb{R}_{++}$ is continuous. In other words, for any post-tax income function $x^u$, the map $a \mapsto x^u(a, T)$ is continuous on $\mathbb{R}_{++}$.

$(\Rightarrow)$ To prove the converse assertion we assume that $T$ is not marginal-rate progressive and show that the map $a \mapsto x^u(a, T)$ has a discontinuity point in $\mathbb{R}_{++}$.

If $T$ is not marginal-rate progressive, the map $x(y)$ is not concave. Define
\[
y^* := \inf\{y \in \mathbb{R}_+ : x(y)|_{[0,y^*]} \text{ is concave}\}.
\]

\textsuperscript{17}For $x, y \in \mathbb{R}^n$, in increasing arrangement, we say that $x$ is majorized by $y$ if $\sum_{i=1}^k x_i \leq \sum_{i=1}^k y_i$ for $k = 1, \ldots, n-1$ and $\sum_{i=1}^n x_i = \sum_{i=1}^n y_i$. (Marshall et al., 2011, p. 8.)
It is easy to see that \( y^* = \overline{y}_{k^*} \) for some \( k^* \in \{1, \ldots, K\} \). In addition, the restriction of \( x(y) \) to \([\overline{y}_{k^*-1}, \overline{y}_{k^*+1}]\) is convex (here \( \overline{y}_{K+1} := +\infty \)) and \( (x^* := y^* - T(y^*), y^*) \gg 0 \) and \( 0 < 1 - t_{k^*-1} < 1 - t_{k^*} \). Applying Lemma 2 it follows that there exist \( 0 < a^* < a^{**} \) such that

\[
\eta^{**}(x^*, y^*) = 1 - t_{k^*} \quad \text{and} \quad \eta^{**}(x^*, y^*) = 1 - t_{k^*-1},
\]

implying \( x^*(a^*, T) < x^* < x^{**}(a^{**}, T) \) and \( x^*(a, T) \neq x^* \) for all \( a \in (a^*, a^{**}) \). (Refer to Figure 3.) If the map \( a \mapsto x^u(a, T) \) were continuous on \( \mathbb{R}_{++} \), the Intermediate Value Theorem would give \( a \in (a^*, a^{**}) \) with \( x^u(a, T) = x^* \), a contradiction. We conclude that the map \( a \mapsto x^u(a, T) \) has a discontinuity point in \( \mathbb{R}_{++} \).
